

Nexus Setup Resource

Give your AI agent a codebase map before it edits anything.

GitNexus indexes your repository into a local knowledge graph so AI coding agents can inspect structure before they edit. The goal is simple: stop your agent from changing code blind.

What Nexus Helps With

GitNexus can help your agent inspect connected files, dependencies, call chains, execution flows, impacted symbols, and likely blast radius before a change.

Best Setup

For real coding work, use CLI + MCP.

Run this from your project root:

```
npx gitnexus analyze
```

```
npx gitnexus setup
```

Then restart your AI editor or coding agent so it loads the MCP server.

Works with agents/editors including Claude Code, Cursor, Codex, Windsurf, OpenCode, and Antigravity. Claude Code has the deepest integration because GitNexus supports MCP tools, skills, and hooks there.

Manual MCP Setup

For Claude Code:

```
macOS / Linux: claude mcp add gitnexus -- npx -y gitnexus@latest mcp
```

```
Windows: claude mcp add gitnexus -- cmd /c npx -y gitnexus@latest mcp
```

For Codex: `codex mcp add gitnexus -- npx -y gitnexus@latest mcp`

For faster startup, install GitNexus globally and run setup instead:

```
npm install -g gitnexus
```

```
gitnexus setup
```

What To Tell Your Agent

"Before you modify this codebase, use GitNexus to inspect the relevant symbols, dependencies, execution flows, and blast radius. If the index is stale, ask me before re-indexing. Do not make broad changes until you understand what the touched code connects to."

Safety Notes

GitNexus is a map, not a guarantee. Still run tests, review diffs, and check risky changes manually.

GitNexus CLI + MCP indexing is designed for local workflows. The README says CLI storage is local, and the web UI can run in-browser or connect to local backend mode.
